Notes:

These are measured consumptions, calculated using a 12dB CF program with ohmic load. In the real world it is possible to occasionally have a crest factor lower than this, though impedances will always be higher than the tested values in those situations.

Thermal dissipation for 1/4 power at 8ohm can be closely approximated using the data of 1/8 power at 4ohm.

Some competitors publish current consumption data using "1/8 Maximum Output Power into a typical 4 Ω loudspeaker", meaning an inductive dummy load with a minimum resistance of 6ohm and not an actual measured load impedance. A typical 4 ohm loudspeaker load will often measure 6 ohms during high output operation, and in the case of subwoofer loudspeaker can reach even near double the rated impedance in the limiting case.
